

## Installation Questions

Posted by rohrbeck99 - 2008/09/08 21:09

---

We're having problems with a new laptop and the AGWA files copied over from the previous laptop. He's getting deliniation errors. I've uninstalled once, that didn't help so that I'd grab a fresh set of installation files. Can someone tell me the difference between install files located in installers folders & the AGWA 2.0 datafiles install? Which should I be using?

The install files in the installers folder are the setup files for the different versions of ArcGIS (currently only 9.0, 9.1, and 9.2 are supported). These programs actually install AGWA onto the computer. The AGWA 2.0 datafiles are not an install per se; the datafiles include a specific directory structure and specific files that AGWA uses. The installers are required for the installation of AGWA and the datafiles are required for you to be able to use AGWA once it is installed.

The reasoning behind separating the installer from the datafiles has to do with file size. The AGWA software is updated more frequently then the datafiles, so it is unnecessary to require users to download the datafiles, which is a much larger download, when there has been no change to the downloads.

If you have access to the AGWA toolbar and tools, then the installation was successful. The datafiles won't be necessary until you reach the parameterization steps. If you are receiving delineation errors, start a new thread focusing on them.
